Abstract : The article marks the jubilee of the phyto-physiologist L. A. Ivanov, corresponding member of the Academy of Sciences USSR, since 1922 (he was born in 1871). He established the interrelationship between the conditions of existence and the means of reproduction of algae. Ivanov's research on P metabolism in plants brought new ideas on the transformation of phosphorous

✓ Significance of viscosity of protoplasm in resistance of plants to high and low temperatures. P. A. Genkel and K. A. Badanova (K. A. Timiryazev Inst. Plant Physiol., Moscow). *Fiziol. Rastenii* 3, No. 5, 455-62 (1959).--Expts. with *Elodea* and sunflower plants showed that with increase of valence of cations supplied to the protoplasm there is an increase in the viscosity of the protoplasm, an increase in the resistance to high temp., and a decrease in resistance to low temps. Low concns. of  $\text{Na}^+$  and  $\text{Ca}^{++}$  increase the hydrophilic nature of protoplasmic colloids,  $\text{Ca}^{++}$  being the more active. Anions of org. salts raise protoplasmic viscosity and lower plant resistance to high and low temps.; hydrophilic nature of the colloids drops. Adaptation of the plants to dry conditions raises the water content of the tissues and raises the hydrophilic nature of the colloids with increase of hydrophilic viscosity of the protoplasm. G. M. K.

TITLE : On Cuticular Transpiration of Plants  
ORIG. PUB. : V sb.: Pamyati akad. N.A. Maksimova, 1957, 32-41  
ABSTRACT : The mid-day rate of transpiration of leaves of long-fibered cotton growing in Vakhshskaya valley steadily dropped during the growing season. The authors explain this decrease by the aging of cuticular transpiration. Determination of cuticular transpiration in leaves of oak (*Quercus*) and birch (*Betula*) in Moscow showed that it was considerably higher in young plants than in old ones. Cuticular transpiration in apricot (*Prunus armenisaca*) and apple (*Pyrus malus*) in Central Asia, although also

Professor

TITLE: Biology Helps Agriculture (Biologiya - sel'skomu khozyaystvu)

PERIODICAL: Nauka i Zhizn', 1957, # 9, p 5-9 (USSR)

ABSTRACT: Soviet biology is following Professor I.V. Michurin's principles by not only trying to explain complex biological phenomena but also by mastering them and on such a basis to transform plant and animal organisms to suit the requirements of man. Michurin's methods led for instance to the development of new varieties of fruit trees which are able to stand the rough climate of Siberia and the Urals. During the long and cold winter, apple trees that spread on the ground are completely covered with snow and are thus well protected against frost. Making plants temperature-resistant is another task of Soviet scientists. By exposing swelled seeds of corn, sugar beet or peas to heat until they are dry, their properties change considerably and the drought-resistance is improved. The cells of such plants are very small and their leaf surfaces very large. In times of drought these plants hold more water than

Card 1/2

Biology Helps Agriculture

the unprocessed ones and produce better crops. Similar methods have been applied to make plants more salt-resistant. Cotton seeds soaked in salt water gave in Azerbaydzhan, on saline soil, crops of 20 - 40 % above the local average. Soviet scientists are pointing out the great importance of microelements for agricultural plants. Experiments conducted in the Ukraine have shown that the use of manganese fertilizers raised crops very considerably.

ABSTRACT: Apart from the work of the experts **Lo Tsung-lo, Ying Hun-ch'ang, Lo Ch'en-ho, T'ang P'ei-sung, Lo Shih-wai**, and others in the field of plant physiology in China, comparatively little has been done yet in the research field of plant stability. Last winter the author of this article was invited by the Institut fiziologii rasteniy Akademii nauk Kitaya (Institute of Plant Physiology of the Chinese AS) to visit the Chinese People's Republic to inform the scientists of that country about some of the research methods and results obtained by Soviet scientists in this field. During his three months' stay he gave fourteen lectures and reports in the cities of Peking, Canton, Nada, and Shanghai; he also performed laboratory experiments. In conjunction with Chinese scientists the cold resistance of plants (Agava Sisalana). the germinative faculty of coffee seeds and others were tested. Thanks to the Institut botaniki Yuzhnogo Kitaya

Card 1/2

Physiology of Plant Stability and Its Investigation in China SOV/30-58-10-14/53

(Botanical Institute of Southern China) it was made possible to carry on investigation in the tropical regions of the country where rubber plants (*Hevea brasiliensis*) are cultivated. Many laboratories are concerned with the study of rice. The author inspected the Pedagogicheskiy universitet Vostochnogo Kitaya (**Pedagogical University of Eastern China**). He also visited the Pekinskaya sel'skokhozyaystvennaya akademiya (**Peking Academy of Agriculture**), the sel'skokhozyaystvennyye instituty v Kantone i Shankhaye (Canton and Shanghai Institutes of Agriculture).

TITLE:

The Process of Protoplasm Isolation as the Second Phase of Winter Wheat Hardening (Protssess obosobleniya protoplazmy kak vtoraya faza zakalivaniya ozimnykh pshenits)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 127, Nr 1, pp 220-223 (USSR)

ABSTRACT:

The plants resistant to frost are characterized by a period of long-lasting and profound rest. The resistance of the tissues of resting plants is determined on the whole by the conditional peculiarities of the plasma (Refs 1-3). The lacking of growth processes (Refs 4-8 for winter wheat), the reduced metabolism intensity as well as the protoplasm separation are characteristic of the period of rest. During the period of rest the content in growth substances is considerably reduced (Refs 9-12). In plants hardened against frost and in a state of rest the protoplasm is characterized by a higher viscosity and by a reduced permeability (Refs 18-19). The physiological processes are of little intensity in winter wheat (Refs 20, 21). The state of rest is of little stability in winter crops. However, if winter wheat is stored during the winter in a warm room for a few days only,

Card 1/4

The Process of Protoplasm Isolation as the Second  
Phase of Winter Wheat Hardening

30V/20-127-1-61/65

the growth processes start quickly in contrast to ligneous plants. The period of rest of the winter crops is very short because no profound transformation of the protective-and supply substances takes place in their cells and because they have no reserve fat which guarantees a stable state of rest (Ref 3). The transition to the state of rest takes place under the influence of autumn conditions of temperature and light. Under the same circumstances the hardening of the plants against low temperature takes place. Thus the transition to the period of rest and the hardening occur during the same period in the life of plants, and both reflect the same processes during the course of which the plants attain the resistance to frost. The hardening is attained in two stages: 1) accumulation of carbohydrates; 2) change of the physico-chemical protoplasm properties (Ref 2). In the present paper the cyto-physiological state of the winter wheat was investigated. The observations of the authors confirmed that the protoplasm becomes peeled off from the cell-coverings in the late autumn- and winter period. The degree of the state of rest differs in the individual organs of the winter wheat. The state of rest of the leaves

Phase of Winter Wheat Hardening

SOV/20-127-1-61/65

is not long. The protoplasm is partly detached only in a few epidermic cells. In autumn and winter, a concave plasmolysis is predominant. At the turn of the year many damaged and dead cells appear. The most complete rest (according to the number of cells with separated protoplasm), and the most stable (according to the length of separation) were found in the growth cone and in the tillering knots (Fig 1). The observations of the authors showed: 1) that the protoplasm separation from the cell walls begins after the first stage of the hardening, that is the accumulation of the soluble carbohydrates in the cells, and 2) that this separation begins at slight frost. In other words, the conditions of the separation process of the protoplasm are exactly the same as those at which the second stage of hardening of the winter crops is attained which is connected with the physico-chemical changes of the

Card 3/4

The Process of Protoplasm Isolation as the Second  
Phase of Winter Wheat Hardening

S07/20-127-1-61/65

protoplasm. The said separation occurs obviously just in the second hardening stage and forms the final stage of the development of the resistance to frost of the winter crops under autumn conditions. There are 1 figure, 1 table, and 22 references, 21 of which are Soviet.

AUTHORS:

Bodrov, V. A., Genkin, A. A., Zarakovskiy, G. M.

TITLE:

Some rules in the reaction of humans to text problems which model the difference between two possible solutions. Report I. The dependence of the error frequency upon the complexity and the probability of the signal

PERIODICAL: Referativnyy zhurnal, Matematika, no. 7, 1962, 78-79, abstract 7V384. ("Dokl. Akad. ped. nauk RSFSR", 1961, no.5,77-80)

TEXT:

The results of the following experiments are described: The test person must answer as quickly as possible with "yes" or "no" to the question whether the number given him orally is divisible by three. Fifteen test persons were told a total of 6286 numbers. It was found: The probability of the error is larger if the less probable signal (a number divisible by three) was given; the probability of the error grows in general with the complexity of the number (number of digits). The influence of the previous signal on the error probability is discussed.

AUTHOR: Genkin, A. A.

TITLE: Revelation of a specific local reaction of the brain in an electroencephalogram during complex activity

PERIODICAL: Referativnyy zhurnal. Matematika, no. 6, 1961, 78-79, abstract 6V430 (Vopr. psikhologii, no. 6, 1961, 114-126)

TEXT: The correlations between the three channels of electroencephalograms are studied. Three bipolar electrodes are fitted above the left cerebral hemisphere (in the Brodman fields 39, 37, and 18) and are switched so that any two of the three electroencephalogram channels have a common electrode (Jasper circuit). The electroencephalogram pairs are processed by the formula

$$\rho = \frac{\sum x_i y_i}{\sqrt{\sum x_i^2 \sum y_i^2}}$$
